

A photograph of a busy Wellington street. In the foreground, a white car is driving towards the camera. To its left, a grey car is also visible. In the background, a green bus with 'Dunedin Park' on its destination sign is driving. Further back, a blue truck and a white van are visible. The street is lined with traffic lights and signs. In the background, a hillside is covered with many colorful houses, and a large green hill rises behind them under a clear sky.

C.1 AM Peak

C.2 Inter Peak

C.3 PM Peak

Appendix D Vehicle travel times validation

1. Introduction

This technical note is part of a series documenting the 2019-2023 update of the Wellington Regional Transportation Planning Analytical Tools. The higher-level Analytical Tools are maintained and operated by Greater Wellington Regional Council (GWRC), who is the client for this project. This project is being delivered by Stantec and Jacobs, supported by GWRC transport modellers.

This note details the validation of the Wellington Transport Strategy Model (WTSM), which aims to demonstrate that the model is a good representation of transport patterns in the base year 2018, by comparing output against a range of observed data:

- Traffic counts and screenlines volumes for light and heavy/medium vehicles
- Traffic travel times
- Bus passengers ticketing information and CBD cordon counts
- Bus travel times
- Rail counts and loading profiles
- Active mode counts

Convergence of the demand model assignment is also reported to demonstrate that the WTSM converges satisfactorily. Convergence of the model in terms of iterative calculation of demand through to assignment is also reported to demonstrate that the WTSM converges satisfactorily.

The criteria used for the model validation are mostly based on the Transport Model Development Guidelines (TMDG), developed by Waka Kotahi. Under the TMDG definition, WTSM is a model of category A, or 'Regional' and criteria for this model category was used.

'TN4 – Data Analysis' details the data that has been used for the validation and how it has been processed.

2. Road assignment validation

2.1 Screenlines and criteria

The 16 screenlines used for the validation of the previous version of the WTSM, comprising a total of 66 counts, were adopted for this new model. However, data for an additional 12 screenlines and 41 counts was also collected which were added to the validation dataset. Description of the screenlines and traffic counts is included in TN4, and their locations are shown in the following figures.

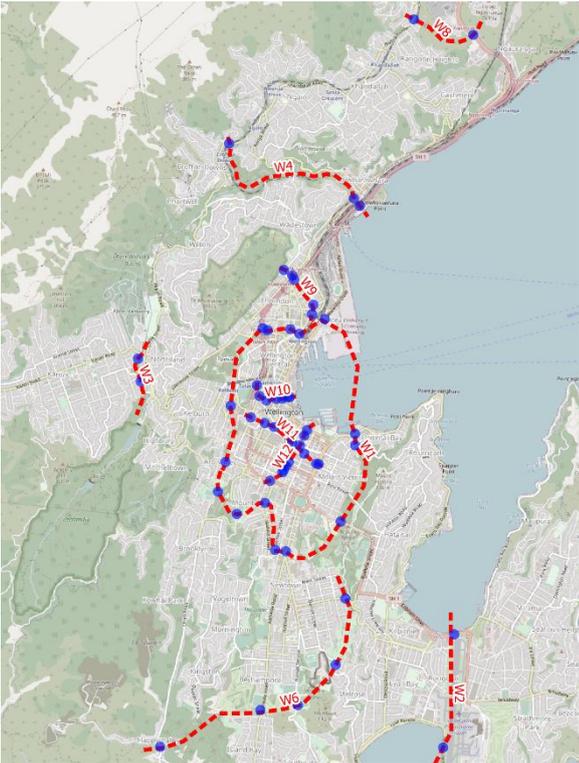

Figure 2.1: Screenlines Wellington

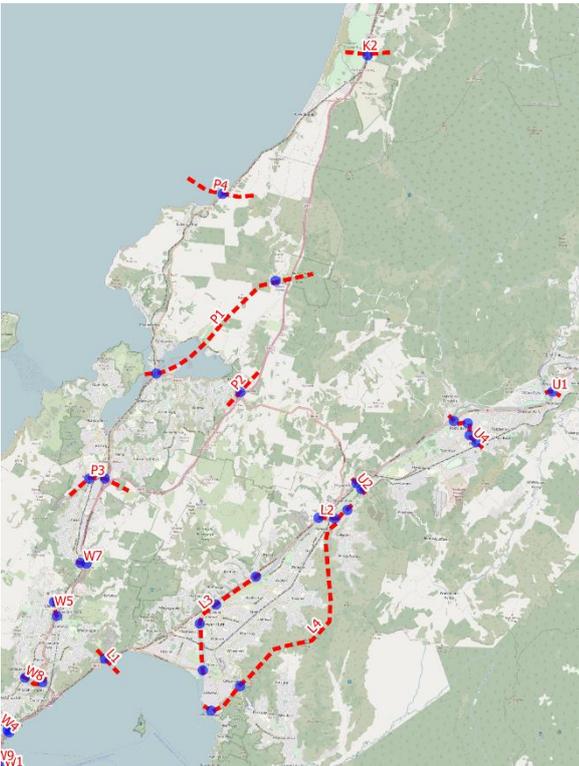

Figure 2.2: Screenlines Hutt Valley and Porirua

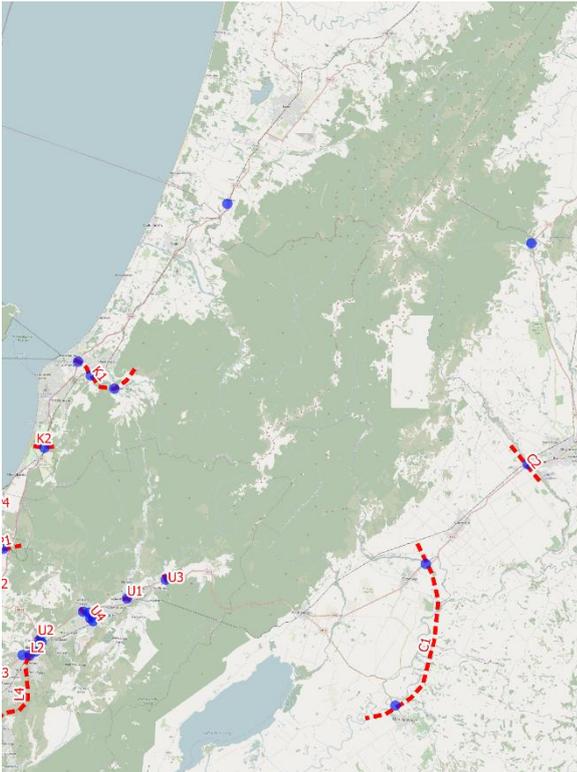

Figure 2.3: Screenlines rest of region

Validation criteria for traffic counts and screenlines is based on the TMDG appropriate for this regional model. The following table shows the criteria for the GEH statistics, used to compare observed and modelled counts.

Table 2.1: Hourly GEH comparison criteria for road traffic count validation

GEH	% of screenlines (per direction)	% of traffic counts (per direction)
GEH <5	>60%	>65%
GEH <7.5	>75%	>75%
GEH <10	>90%	>85%
GEH <12	N/A	>95%

The targets for the GEH statistic are based on hourly volumes, but the modelled periods in WTSM are longer than a single hour. The method employed in previous updates of WTSM was to divide the 2-hour observed and modelled flows by two to generate an "average hour" flow. The same approach was applied for the 3-hour AM and PM peak periods in the new model, as well as for the 6-hour Inter-peak period. For the 12-hour Overnight period however, a factor of seven was used to divide observed and modelled flows, as many hours during this period have very low volumes which would make the GEH look artificially better.

In addition to the GEH comparison, the TMDG specifies the following criteria:

- Screenline hourly count bands:
 - >70% within 10%
 - >80% within 15%
- Link hourly counts bands:
 - For links with directional volumes less than 700 vph (vehicles per hour): >70% within 100vph
 - For links with directional volumes between 700 and 2700 vph: >70% within 15%
 - For links with directional volumes above 2700 vph: >70% within 400vph
- Scatterplots of modelled vs observed for all traffic counts, line of best fit with:
 - R² greater than 0.85

- Slope line of best fit (forced through zero) between 0.9 and 1.1
- RMSE (root mean squared error) for all counts:
 - Acceptable: less than 30%
 - Requires clarification: between 30% and 40%
 - Unlikely to be appropriate: greater than 40%

Turning movements are not validated, as this is not required or appropriate for a strategic model of category A.

Validation was carried out separately for light vehicles, and medium and heavy vehicles combined (called 'heavy vehicle' in the rest of this note for simplicity).

2.2 Screenline validation – Light vehicles

The following table shows a summary of the light vehicles' validation against observed volumes (average hour) across screenlines. Results are also presented in scatterplot format, where flows for the modelled period are plotted.

Values shaded in grey in the validation tables throughout this note are values that do not meet TMDG criteria.

Table 2.2: Screenline validation – light vehicles

Criteria		AM	IP	PM	ON
GEH	>60% with GEH<5	69%	70%	73%	69%
	>75% with GEH<7.5	83%	81%	83%	86%
	>90% with GEH<10	91%	91%	91%	94%
% Difference	70% with difference <10%	50%	58%	59%	42%
	80% with difference <20%	79%	77%	82%	65%

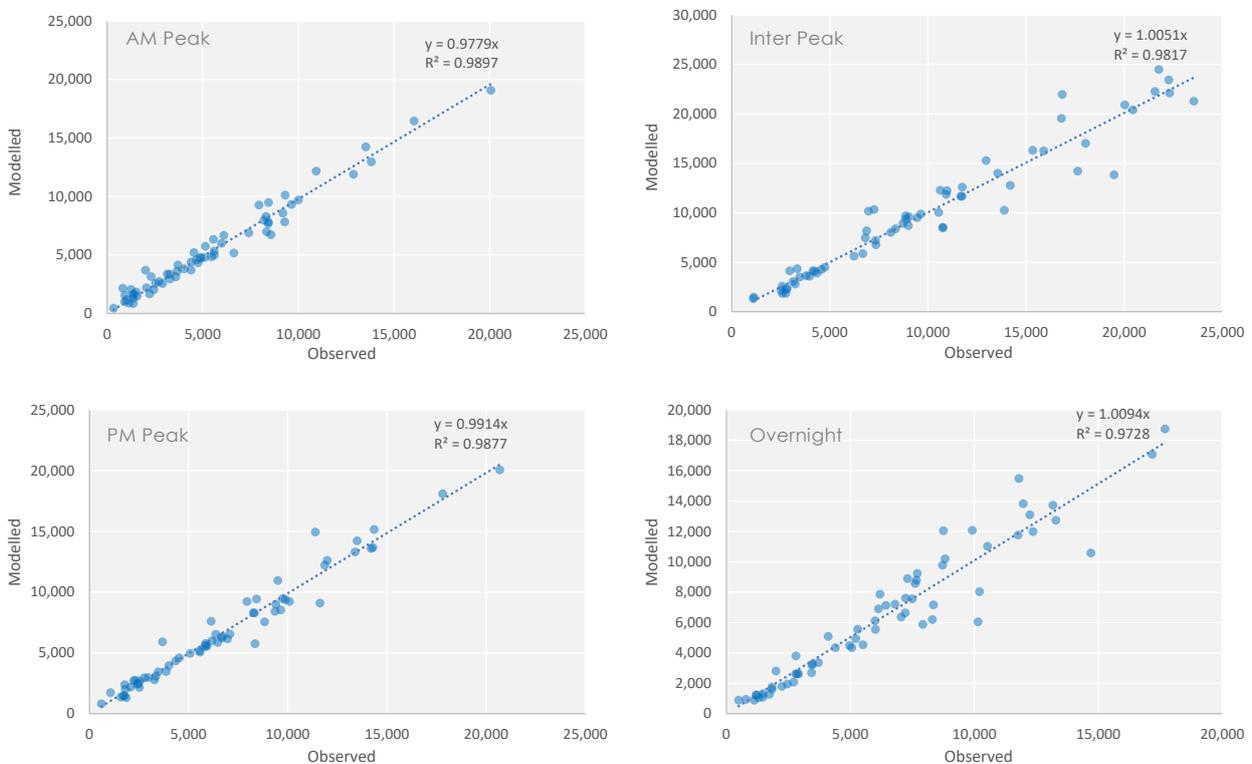

Figure 2.4: Screenline validation scatterplots – Light vehicles (period flows)

At an aggregate level, results show that all of the GEH criteria are met. In most cases, the model performs largely above the TMDG criteria.

Looking at percentage difference with observed, the model does not meet any of the TMDG guidelines. It is generally well below the first criteria, and slightly under the second one. This is consistent with our experience with other strategic models for which achieving these thresholds appears very difficult even if all other metrics are met.

Looking at detailed results per screenline (which are included in Appendix A), the following comments can be made:

- Screenline W1 was broken down in 4 sections (W1A to W1D) to separate movements from the East, South, West and North to the CBD. Most movements show a GEH under 5 for all time periods. The worst performing is the CBD South (W1A) outbound in the PM peak, with a GEH of 10.
- The CBD cordon screenline as a whole (W1) shows GEH of respectively 1 and 4 for the critical AM inbound and PM outbound movements, showing that the model is a good representation of peak direction trips to and from the CBD.
- Two of the newly added screenlines within the CBD (W11 and W12) show low levels of validation, consistently under-predicting traffic volumes. This is unsurprising due to a strategic model such as WTSM having limitations in representing central city patterns, with trips allocated to their destination zone and not parking zone, and parking circulation not represented. This must be taken into consideration when interpreting results from the model however.
- Outside of the CBD, the main outliers are screenlines Lower Hutt East and Lower Hutt Central (respectively L4 and L3) with GEH up to 18. The model generally overestimates by 25%-30% traffic from/to the East of Lower Hutt through L4, which then also impacts L3 to a lesser extent. Peak direction traffic is however a better match with respectively 17% and 12% (GEH 8 and 6) in the AM and PM peak periods.
- The Karori screenline (W3) also shows a 25-30% overestimation from the model, although GEH are mostly between 5 and 10 due to the lower volumes.
- The screenline U3 which includes a single count on the SH2 Rimutaka Hill Rd shows a significant difference with modelled volumes being higher than observed, especially in the peak direction. However, both nearby screenline U1 and a screenline on the other side of the Rimutaka Hill (C1) show the model being a good match with observed, even showing a slight underestimation. The level of landuse activity between U3 and U1 is unlikely to generate the 14,000 daily trips difference between the two screenlines and therefore no further adjustments were made to match this count. It is however recommended that this is investigated should further observed data become available.
- Other strategically important screenlines on the State Highway network such as Miramar (W2), Kaiwharawhara (W4), Churton Park (W5), Lower Hutt North and South (L2 and L1) and Porirua North and South (P1 and P3) all show good performance, with most GEH values under or slightly above 5.

2.3 Individual link validation – Light vehicles

The following table and plots present the validation of light vehicle assignment against observed volumes for individual counts.

Table 2.3: Individual link validation – light vehicles

Criteria	Criteria	AM	IP	PM	ON
GEH	>65% with GEH<5	58%	59%	56%	66%
	>75% with GEH<7.5	78%	79%	80%	81%
	>85% with GEH<10	88%	87%	88%	88%
	>95% with GEH<12	93%	90%	94%	91%
Difference	70% of links with flow<700vph within 100	67%	68%	60%	86%
	70% of links with 700<flow<2700vph within 15%	65%	65%	66%	33%
	70% of links with flow>2700vph within 400	100%	N/A	83%	N/A
Other	r2 > 0.85	0.97	0.96	0.97	0.94
	Slope of trendline between 0.9 and 1.1	0.97	1.02	0.98	1.02
	RMSE <30%	26%	28%	24%	36%

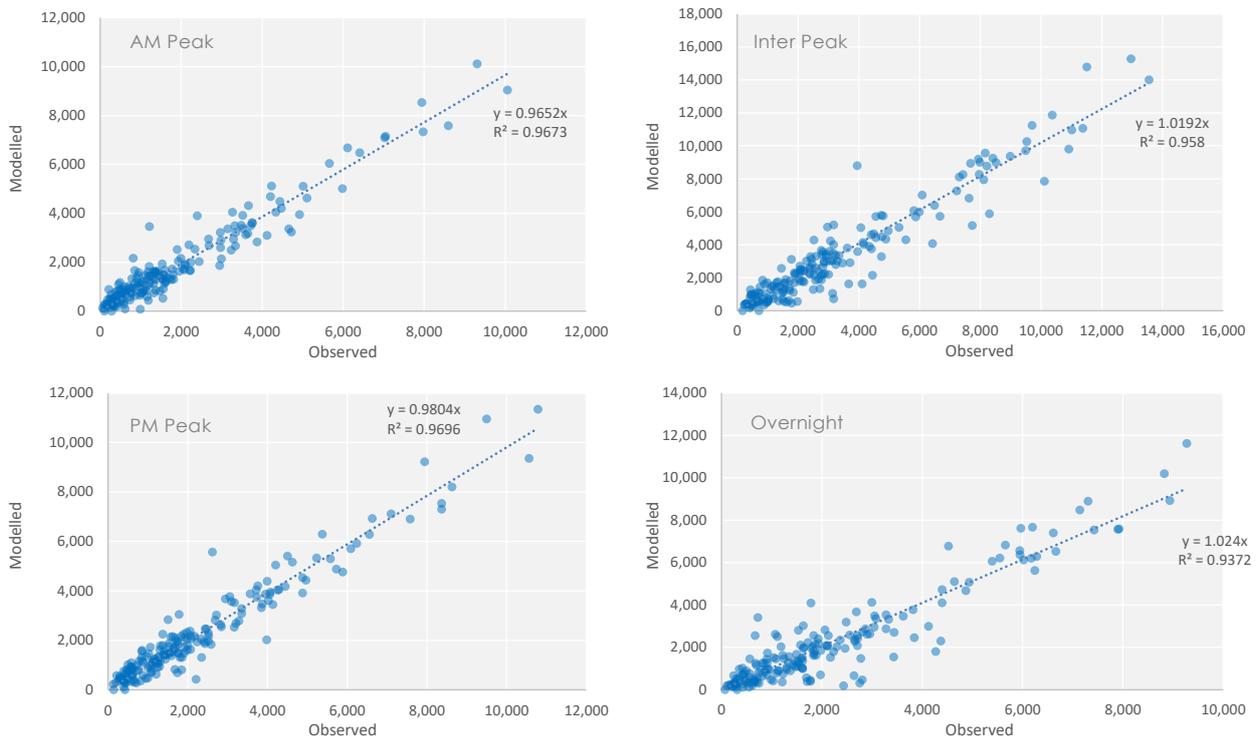

Figure 2.5: Individual link validation scatterplots – Light vehicles (period flows)

The summary of validation for individual links shows that the model fails to match the TMDG criteria for links below GEH 5 and to a lesser extent GEH 12. It achieves criteria for GEH 7.5 and 10 however. Similarly, the model is below the criteria for volume differences in most cases, although generally close. Again, our experience with other strategic models shows that these thresholds are generally difficult to achieve, and results for this version of WTSM, which achieves over half of the GEH criteria, is a significant improvement on previous versions of the model.

For all other metrics the model achieves the TMDG guidelines, with the exception of RMSE for the Overnight period.

In most cases, the main outliers are consistent with screenline results, with counts on L3, L4 and W3 reflecting the over-estimation of volumes over these screenlines, and the model underestimating flows for W11 and W12.

2.4 Screenline validation – Heavy vehicles

The following table shows the heavy vehicles validation against observed volumes across screenlines. Results are also presented in scatterplot format.

Table 2.4: Screenline validation – heavy vehicles

Criteria		AM	IP	PM	ON
GEH	>60% with GEH<5	80%	83%	79%	85%
	>75% with GEH<7.5	92%	95%	91%	95%
	>90% with GEH<10	97%	97%	97%	97%
%	70% with difference <10%	18%	17%	24%	8%
	80% with difference <20%	32%	30%	39%	20%

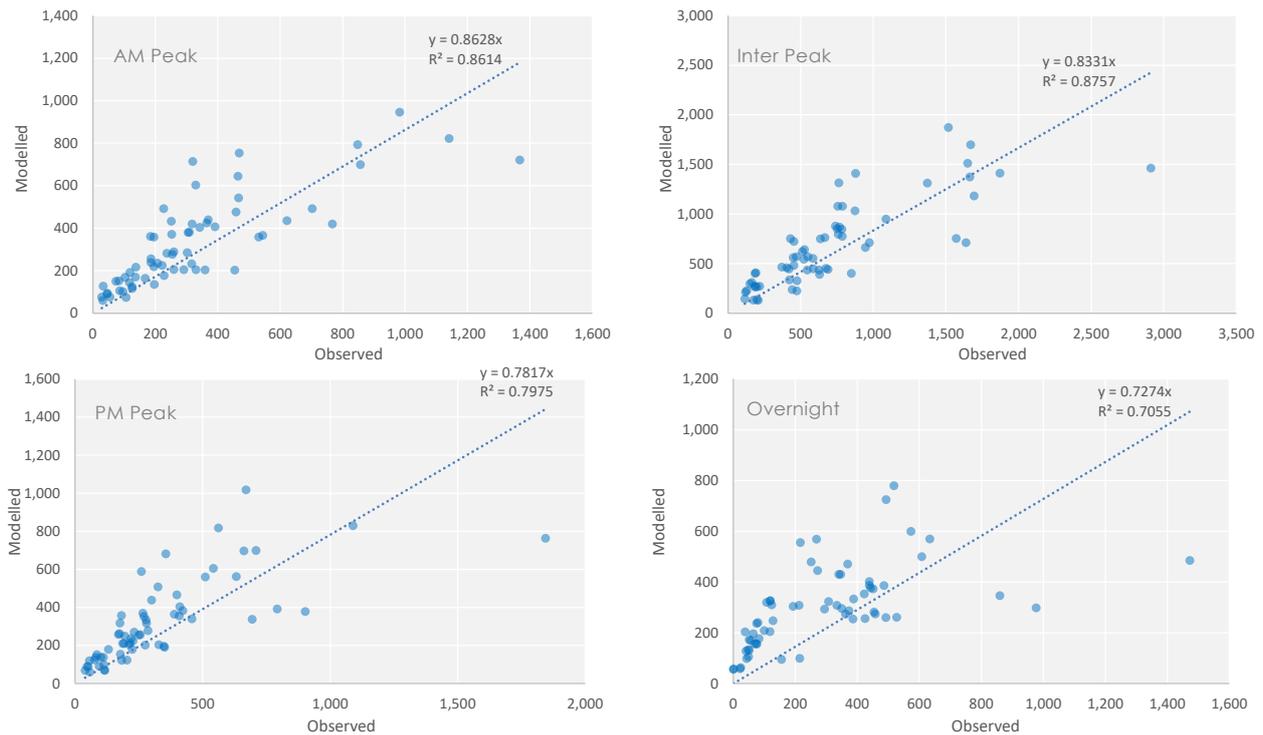

Figure 2.6: Screenline validation Scatterplots – Heavy vehicles (period flows)

The detailed results per screenline are included in Appendix A.

While the GEH criteria are all achieved, this is because the heavy vehicles flows are numerically small and the GEH statistic is tolerant of differences. It is also noted that the targets in the TMDG are not specifically for different vehicle types.

For percentage differences, none of the targets are achieved and the heavy vehicle flows are a long way from the targets. Again, this is a reflection of modelling very small flows. For example, for the average hour in the AM peak, the observed heavy vehicle flows range from zero to 300, with the overall average (simple average across all links) is 37 vehicles.

The scatter plots for the AM, Inter-peak, and PM peak periods shows a reasonable relationship, albeit not as tightly clustered as for light vehicles. The Overnight overestimates at most locations although the flows are relatively small in comparison to the other periods.

2.5 Individual link validation – Heavy vehicles

The following table and plots present the validation of heavy vehicle assignment against observed volumes for individual counts.

Table 2.5: Individual link validation – heavy vehicles

Criteria	Criteria	AM	IP	PM	ON
GEH	>65% with GEH<5	83%	82%	81%	90%
	>75% with GEH<7.5	95%	95%	93%	99%
	>85% with GEH<10	98%	98%	98%	99%
	>95% with GEH<12	99%	99%	99%	99%
Difference	70% of links with flow<700vph within 100	98%	99%	97%	100%
	70% of links with 700<flow<2700vph within 15%	N/A	N/A	N/A	N/A
	70% of links with flow>2700vph within 400	N/A	N/A	N/A	N/A
Other	r2 > 0.85	0.67	0.64	0.54	0.56
	Slope of trendline between 0.9 and 1.1	0.80	0.73	0.63	0.62
	RMSE <30%	90%	91%	114%	118%

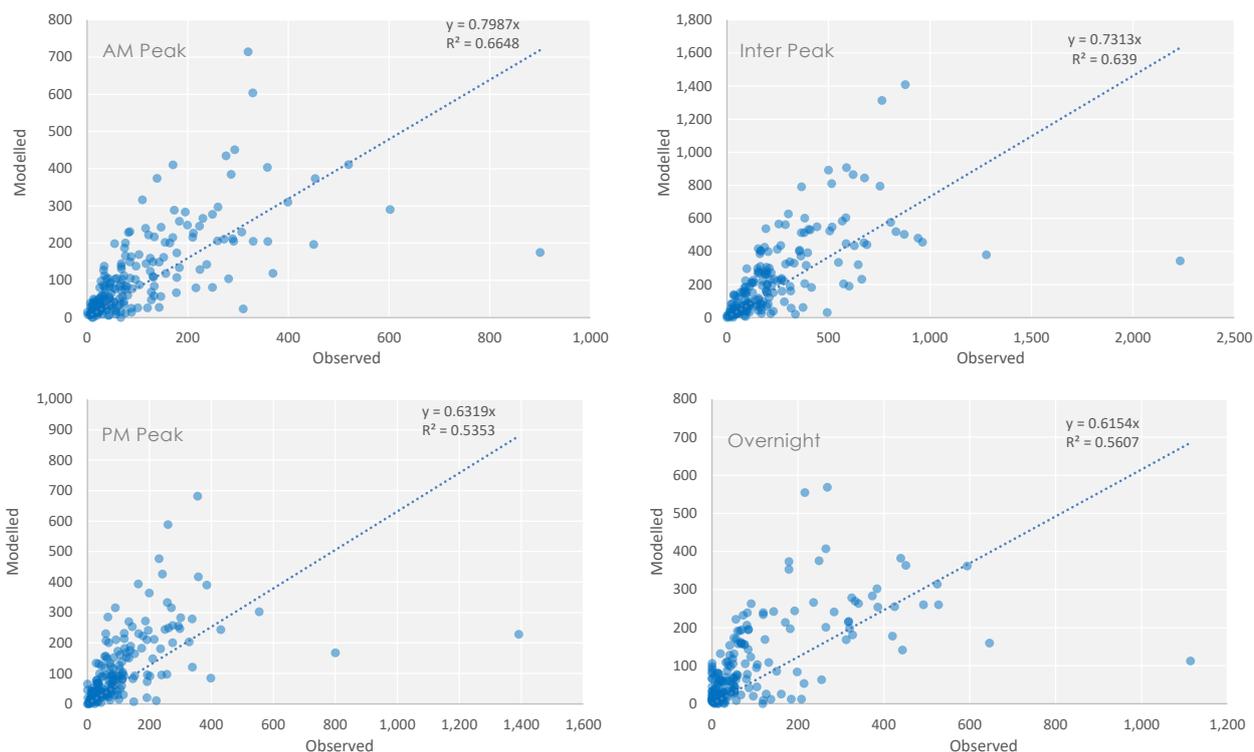

Figure 2.7: Individual link validation Scatterplots – Heavy vehicles (period flows)

Again, while the GEH and the difference targets are all achieved, these are not good metrics for heavy vehicles which are small in magnitude. Similarly, the modelled RMSE values are significantly higher than the target, but RMSE will always be high for low volume roads and so is also not a good measure for heavy vehicle flows.

The r-squared and the slope of the trendline do not meet the targets. The graphs in Figure 2.7 show a relative amount of scatter but also that the flows are small in volume.

While there is notable variation in the heavy vehicle flows, particularly at link level, they are difficult to replicate in a synthetic model and numerically less significant.

2.6 Screenline validation – Total vehicles

Finally, the following table and scatterplots shows results for total vehicles, including light and heavy.

Table 2.6: Screenline validation – total vehicles

Criteria		AM	IP	PM	ON
GEH	>60% with GEH<5	64%	69%	70%	69%
	>75% with GEH<7.5	84%	81%	83%	86%
	>90% with GEH<10	89%	91%	91%	92%
% Difference	70% with difference <10%	50%	59%	59%	42%
	80% with difference <20%	80%	76%	82%	67%

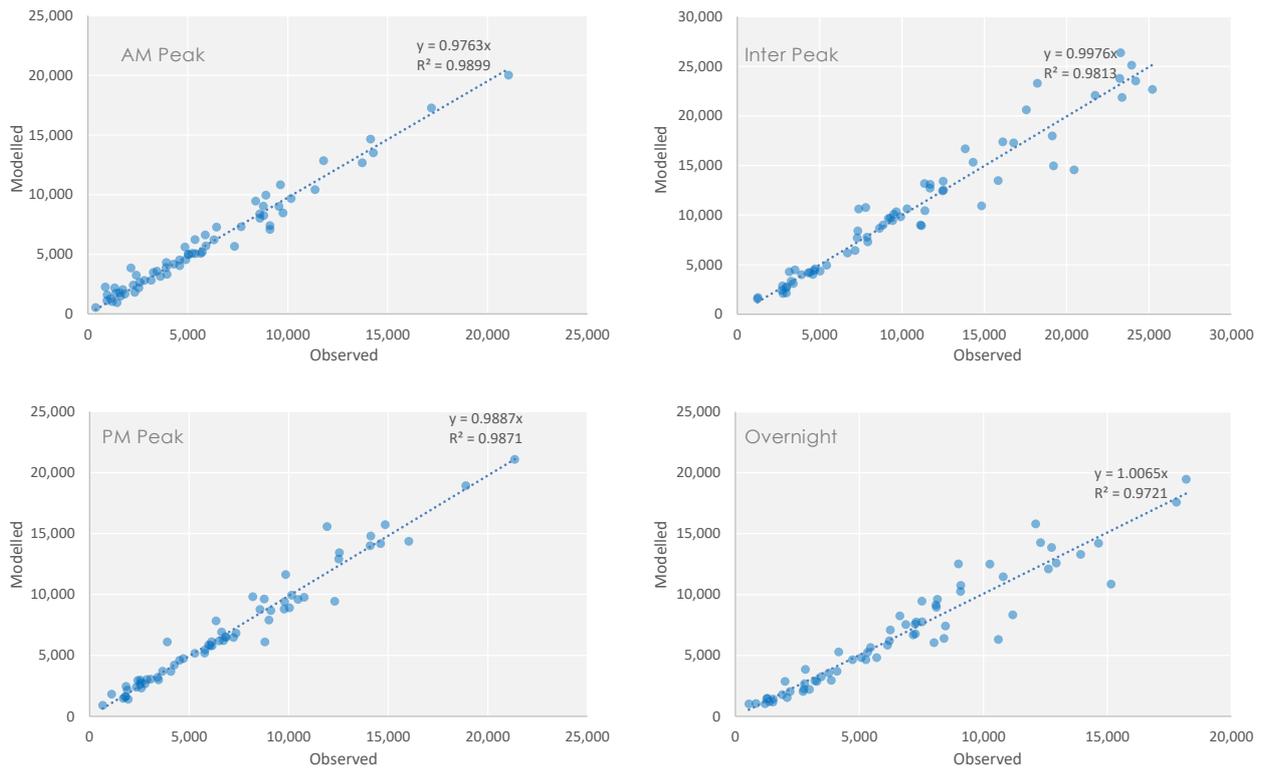

Figure 2.8: Screenline validation scatterplots – Total vehicles (period flows)

Results are overall similar to light vehicles, as these represent the large majority of volumes.

2.7 Individual link validation – Total vehicles

The following table and plots present the validation of total vehicle, including light and heavy, against observed volumes for individual counts.

Table 2.7: Individual link validation – total vehicles

Criteria	Criteria	AM	IP	PM	ON
GEH	>65% with GEH<5	60%	59%	56%	64%
	>75% with GEH<7.5	76%	77%	78%	80%
	>85% with GEH<10	87%	85%	86%	87%
	>95% with GEH<12	91%	89%	92%	90%
Difference	70% of links with flow<700vph within 100	64%	68%	61%	85%
	70% of links with 700<flow<2700vph within 15%	64%	62%	61%	33%
	70% of links with flow>2700vph within 400	80%	N/A	71%	N/A
Other	r2 > 0.85	0.97	0.95	0.97	0.93
	Slope of trendline between 0.9 and 1.1	0.97	1.02	0.98	1.02
	RMSE <30%	26%	30%	25%	37%

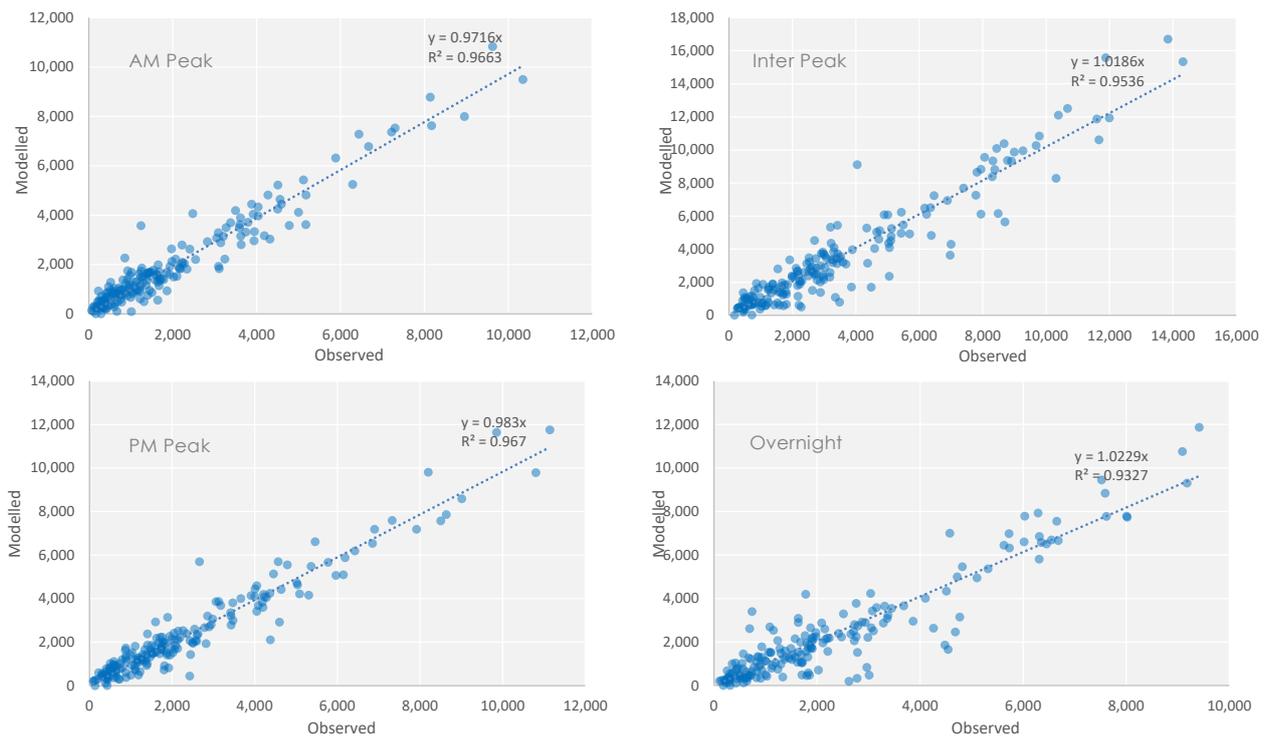

Figure 2.9: Individual link validation scatterplots – Total vehicles (period flows)

Again, results are similar to light vehicles only.

3. Private vehicles travel times

This section details the validation of modelled travel times for light vehicles as calculated through the WTSM traffic assignment, against observed travel times extracted from GPS information. Details of how this data was sourced and processed can be found in 'TN4 – Data Analysis'.

Eight routes were used for the travel times validation:

- Route 1: Masterton to Wellington Airport via SH1 and SH2
- Route 2: Paekakariki to Island Bay via the Waterfront
- Route 3: Centreport to Seaview
- Route 4: Newlands to Wellington Rail Station via Hutt Road
- Route 5: Karori to Miramar via Waterfront and Evans Bay
- Route 6: Waterfront to Airport via Adelaide Rd and Kilbirnie
- Route 7: Seatoun to Wellington Station via Taranaki St and Waterfront
- Route 8: Paremata to Haywards via SH58

These routes are shown in the following figures.

Figure 3.1: Travel time validation routes

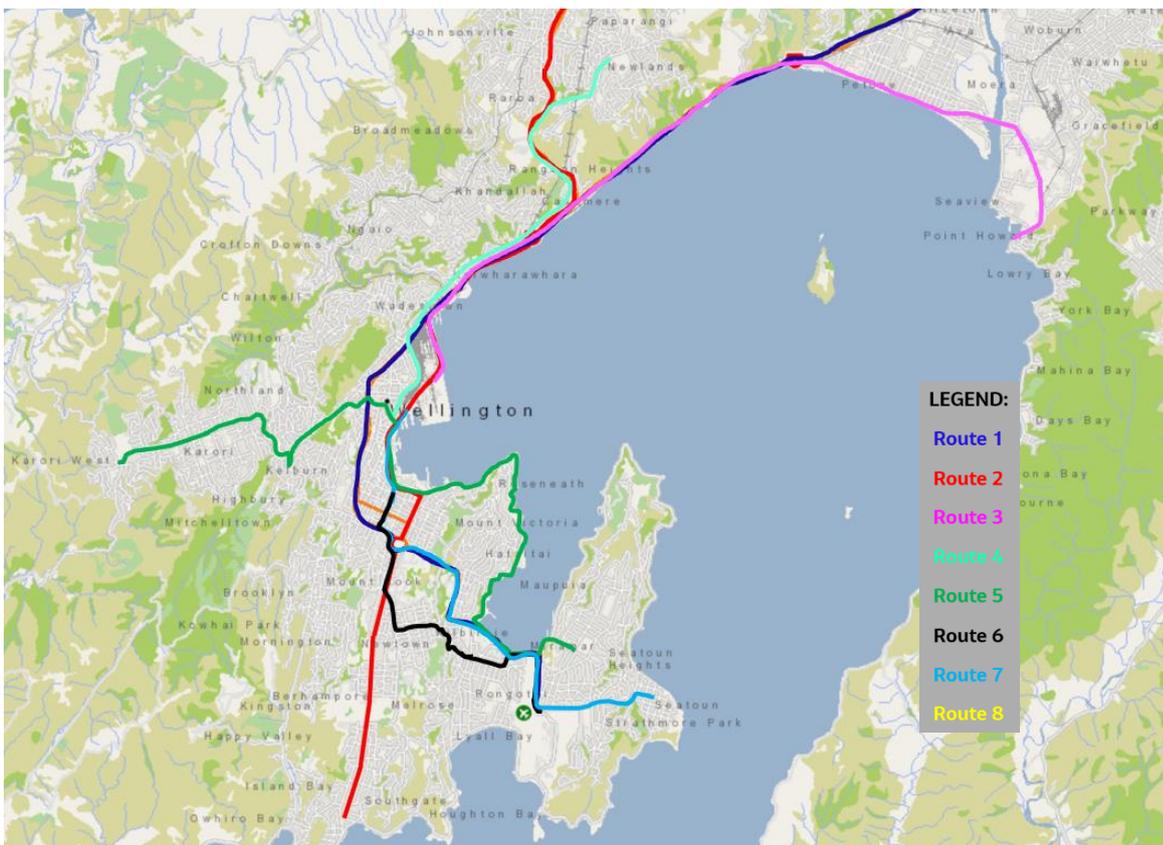

Figure 3.2: Travel time validation routes - Wellington

The TMDG specifies the following criteria:

- 80% of routes within 15% or 1 minute (if higher)
- 85% of routes within 25% or 1.5 minute (if higher)

A summary of the travel time validation is shown in the following table.

A more detailed comparison of observed and modelled travel time profiles for each route and direction is included in Appendix D. Traditionally these graphs show the mean observed travel times, along with the

minimum and maximum. In this case however, due to the travel time data being sourced from GPS information, minimum and maximum times reflect minimums and maximums experienced at each particular point along the route. Summing minimums/maximums over the whole route does not result in a minimum/maximum journey time experienced in reality. The time +/-15% were used as an alternative.

Finally, for the AM and PM peak periods both the peak hour and the shoulder periods are assigned separately in WTSM, however validation is carried out for the peak period as a whole. Modelled and observed travel times were therefore extracted for both peak hour and shoulders, and the weighted average was calculated to produce times for the whole AM and PM peak periods.

Table 3.1: Travel time validation

Route and direction		AM Peak				Inter Peak				PM Peak			
		Obs	Mod	within 15% or 1min	within 25% or 1.5min	Obs	Mod	within 15% or 1min	within 25% or 1.5min	Obs	Mod	within 15% or 1min	within 25% or 1.5min
Route 1	NB	112	107	Y	Y	108	104	Y	Y	124	128	Y	Y
	SB	129	148	Y	Y	113	107	Y	Y	116	117	Y	Y
Route 2A	NB	54	52	Y	Y	53	51	Y	Y	72	68	Y	Y
	SB	69	66	Y	Y	54	51	Y	Y	60	55	Y	Y
Route 3	NB	18	17	Y	Y	19	18	Y	Y	24	31	N	N
	SB	35	43	N	Y	19	18	Y	Y	18	22	N	Y
Route 4	NB	15	13	Y	Y	14	13	Y	Y	15	16	Y	Y
	SB	20	19	Y	Y	14	11	N	Y	15	13	Y	Y
Route 5	EB	32	29	Y	Y	30	26	Y	Y	32	32	Y	Y
	WB	34	31	Y	Y	31	27	Y	Y	39	35	Y	Y
Route 6	EB	18	16	Y	Y	20	15	N	Y	23	20	Y	Y
	WB	19	17	Y	Y	19	15	N	Y	25	17	N	N
Route 7	EB	20	21	Y	Y	21	20	Y	Y	25	25	Y	Y
	WB	28	25	Y	Y	22	21	Y	Y	34	25	N	N
Route 8	EB	14	13	Y	Y	14	13	Y	Y	13	15	Y	Y
	WB	16	18	N	Y	14	13	Y	Y	13	14	Y	Y
Routes within guidelines				88%	100%			81%	100%			75%	81%
Target				80%	85%			80%	85%			80%	85%

Results show that overall, the model tends to slightly under-estimate travel time, being circa 3% too fast in total. This is considered acceptable and the model meets TMDG guidelines for all cases except the 'within 15% or 1 minute' criteria in the PM peak, where it falls short by one route.

The main outliers are:

- Route 3 (Centreport to Seaview) is about 20% too slow southbound in the AM peak and northbound in the PM peak, i.e. in the peak direction. Most of the difference occurs on SH2 between Lower Hutt and Ngauranga which is highly congested.
- Route 6 (Waterfront to Airport) and 7 (Seatoun to Wellington Station) are 25-30% too fast southbound in the PM peak (and Interpeak for route 6).

4. Bus patronage

4.1 Summary

Bus assigned patronage was validated using a subset of the screenlines used for traffic volumes, with some removed as they are not crossed by any bus routes.

The TMDG specifies criteria for the validation of public transport, as shown in the following table.

Table 4.1: Hourly GEH comparison criteria for public transport patronage validation

GEH	% of screenlines (per direction)	% of traffic counts (per direction)
GEH <5	>60%	>50%
GEH <7.5	>70%	>60%
GEH <10	>80%	>70%
GEH <12	>90%	>85%
Line of best fit – slope	y=0.9x to 1.1x	y=0.85x to 1.15x
R ²	>0.85	>0.80

Unlike traffic counts, no observed public transport patronage was available across screenlines. Instead, the same process to extract observed bus volumes as for the validation of the Wellington Public Transport Model (WPTM) was used as detailed in 'TN15 – WPTM validation'. As a summary, a "reference" assignment was carried out, with observed bus matrices derived from electronic ticketing information assigned to the bus network to derive observed volumes. While this approach can potentially lead to some routing error in assigning the observed demand, the topography and absence of alternative routes for most Wellington PT corridors mean that this represents a reliable proxy for observed bus volumes at a screenline level.

The approach used to derive the observed matrices from ticketing data was the same as for WPTM, but based on the longer WTSM time periods.

4.2 Screenline validation

Validation results for screenlines are shown in the following table which shows the GEH, slope of the trendline, and r-squared. Modelled volumes associated with the 'Flyer' bus services to/from the airport have been removed for consistency as they are not included in the ETM data. Volumes are shown for the whole modelled periods, however, for the GEH calculation period flows were converted to average hour by dividing by the number of hours in each period.

Table 4.2: Screenline validation – bus patronage

Criteria		AM	IP	PM	ON
GEH	>60% with GEH<5	78%	72%	61%	87%
	>70% with GEH<7.5	85%	87%	72%	98%
	>80% with GEH<10	93%	93%	85%	100%
	>90% with GEH<12	100%	98%	91%	100%
Other	Slope of trendline between 0.9 and 1.1	0.92	0.94	0.90	0.93
	r ² > 0.85	97%	93%	97%	92%

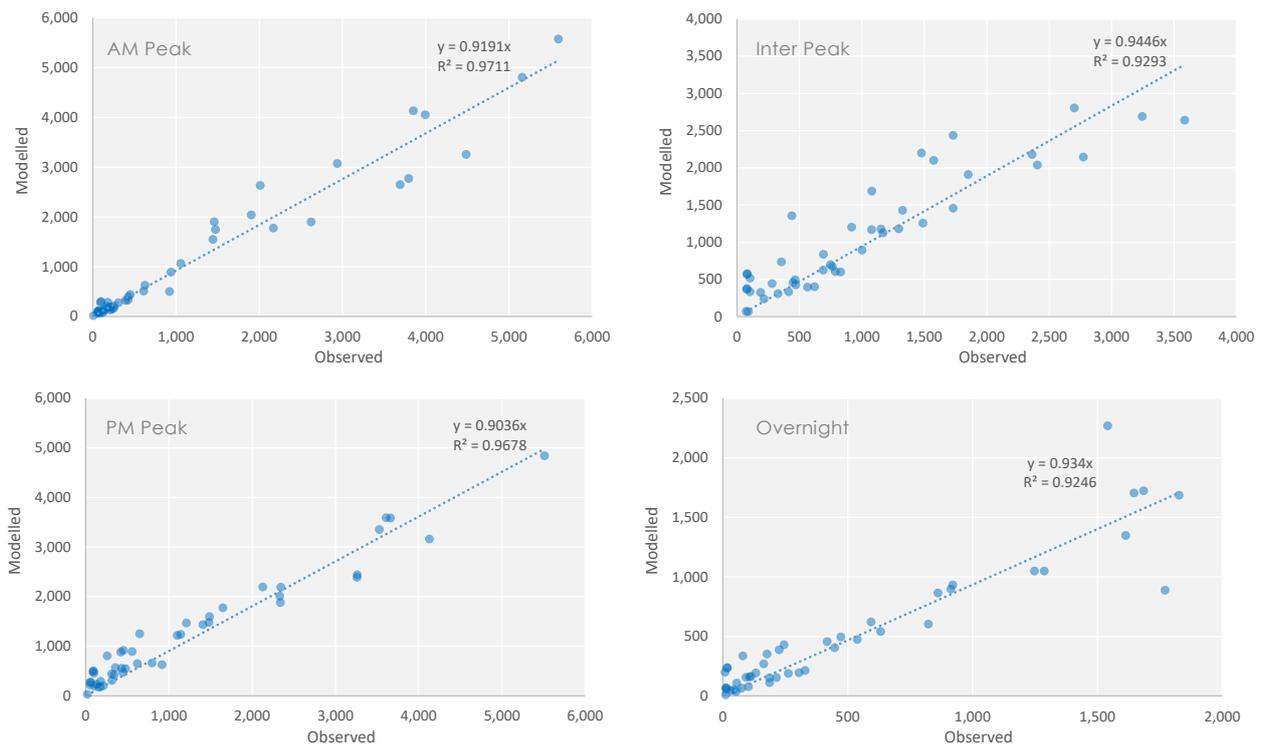

Figure 4.1: Screenline validation scatterplots – Bus patronage (period flows)

Results show that overall the model meets all the TMDG guidelines, with scatterplots also showing a close match between modelled and observed volumes. The slope indicates a slight tendency of the model to underestimate demand, between 5 and 8% depending on the time period.

The detailed results per screenline are included in Appendix B and the following observations can be made:

- The total number of bus passengers from and to the CBD through screenline W1 is a good match with observed, with GEH smaller than 5 for all time periods and both directions.
- Results are also good overall if looking at patronage to/from the CBD on different corridors (W1A to W1D). The main exception is between the CBD and the North, which shows a circa 30% underestimation in the peak direction, with a GEH of 11 in the AM peak.
- The same issue can be seen on screenlines further north (W4) and south (W9) on the same corridor which indicates an underestimation of bus patronage between North Wellington and the CBD. It must however be noted that data from the CBD cordon counts shows lower patronage on this corridor (see section 4.4). It is therefore recommended that this discrepancy is investigated in more detail should appropriate patronage data become available, and that model users take it into consideration in the meantime.
- Results are overall goods in terms of GEH for most other screenlines. In some cases, large relative differences can be observed but these are for corridor, or time period and direction with low volumes resulting in small GEH.

4.3 Individual link validation

The following table and plots present the validation of bus patronage from the public transport assignment against observed volumes for individual locations.

Table 4.3: Individual count validation – bus patronage

Criteria	Criteria	AM	IP	PM	ON
GEH	>50% with GEH<5	84%	88%	75%	94%
	>60% with GEH<7.5	94%	93%	86%	94%
	>70% with GEH<10	98%	97%	96%	94%
	>85% with GEH<12	100%	99%	96%	94%
Other	Slope of trendline between 0.85 and 1.15	0.88	0.97	0.89	0.92
	r2 > 0.8	97%	90%	96%	89%

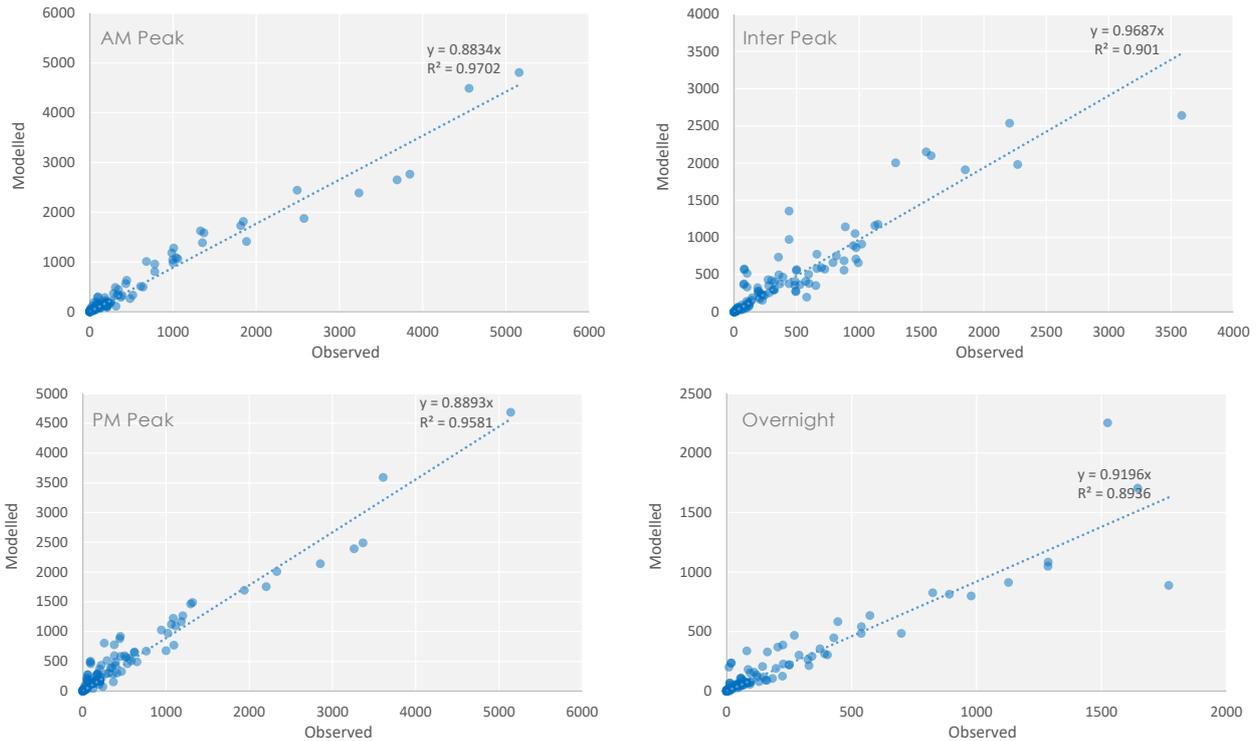

Figure 4.2: Individual counts validation scatterplots – Bus patronage (period flows)

Results for individual links show that overall the model meets all the TMDG guidelines, with scatterplots also showing a close match between modelled and observed volumes.

4.4 Wellington CBD cordon counts

The total number of bus users entering the CBD during the AM peak was compared with the annual CBD cordon survey. Data from March 2019 was used for consistency with the post PT Operating Model network changes and ETM data used.

Necessary adjustments were made to the data:

- The March 2019 bus CBD cordon survey was carried out on a Tuesday and data was factored to average weekday, by applying a factor of 0.98 derived from ETM data.
- The CBD cordon surveys cover the 7-9am period, whereas the modelled AM peak period includes 6-9am. Observed volumes were therefore adjusted using factors also derived from ETM data.
- Finally outbound bus patronage for the 4-6pm period was also surveyed but only in March 2017 before network changes from the PT Operating Model were made. These volumes were used, factored up to 2019 and to 3-6pm as it was considered they would still provide a useful check with modelled volumes.

The following table shows modelled bus volumes across all locations on the CBD cordon, along with observed patronage. Again, the GEH was calculated using an average hour flow.

Table 4.4: CBD Cordon bus passenger validation

Links of CBD Cordon	Observed (3 hour)	Modelled (, 3 hour)	Difference	% Difference	GEH
AM Peak - Inbound					
Oriental Parade	515	640	125	24%	3.0
Cambridge Terrace	1,919	1,830	-89	-5%	1.2
Elizabeth Street	2,607	2,590	-17	-1%	0.2
Willis Street	1,072	1,297	225	21%	3.8
Taranaki Street	1,348	1,004	-344	-26%	5.8
Hawker Street	26	5	-21	-81%	3.1
Tinakori Road	1,451	1,655	204	14%	3.0
Kelburn Parade	1,100	1,154	54	5%	0.9
Murphy Street	520	512	-8	-1%	0.2
Thorndon Quay	3,196	2,817	-379	-12%	4.0
Total	13,756	13,504	-252	-2%	1.2
PM Peak - Outbound					
Oriental Parade	397	528	131	33%	3.5
Kent Terrace	1,945	1,567	-378	-19%	5.2
Elizabeth Street	1,572	1,962	390	25%	5.4
Victoria Street	1,148	1,121	-27	-2%	0.5
Taranaki Street	1,084	804	-280	-26%	5.3
Hawker Street	98	14	-84	-86%	6.5
Tinakori Road	1,421	1,141	-280	-20%	4.5
Kelburn Parade	756	915	159	21%	3.2
Molesworth Street	832	661	-171	-21%	3.6
Thorndon Quay	2,718	2,526	-192	-7%	2.2
Total	11,970	11,239	-731	-6%	3.9

Results show that the model is a good representation of bus patronage entering the CBD in the AM peak period, with all but one corridor showing a GEH smaller than 5, as does the cordon as a whole. Most relative differences are also small. The main exception is Taranaki with a 26% underestimate leading to a GEH of 6.

As noted previously, while modelled volumes are smaller than observed on Thorndon Quay, the difference is far less than compared against the "observed matrix" built from ETM used in the previous section. Being based on a single weekday, results from the CBD cordon tend to fluctuate but volumes from 2018 and 2017 surveys were found to be consistent with 2019 as well.

Results are not as good in the PM peak, although as noted previously, the observed is based on a 2017 survey before network changes and factored to 2019. The difference in patronage is however unlikely to have been significant and these results provide a useful check, showing that the model still provides a suitable representation of observed volume in this time period.

5. Bus journey times

The detailed comparison of bus journey times estimated by the model against observed data is shown in 'TN29 – PT Assignment' which also describes how the travel time functions for buses were estimated.

Modelled travel times were compared against observed for a sample of 25 routes covering the whole region and were found to be a good fit with observed, achieving all validation targets in terms of slope and r-squared.

The TMDG does not have any specific guidelines for bus travel times, simply stating that comparison would be broadly similar to vehicle comparison with some potential relaxing of guideline target levels depending on the focus and purpose of the model.

The table below shows how the model performs against the TMDG validation criteria for private vehicles. As can be observed, the criteria of 80% of routes within 15% or 1 minute is not achieved. This is unsurprising as modelled bus journey times include some error associated with the background traffic travel times as well as additional error related to time components specific to bus (acceleration/deceleration at bus stops, dwell times, bus lanes, etc) and do not generally validate as well as traffic travel times. The second criteria of 85% of routes within 25% or 1.5 minutes is however achieved for all time periods.

Table 5.1: Bus travel times

Time period	Within 15% or 1 minute	Within 25% or 1.5 minute
AM Peak	70%	85%
Inter peak	71%	90%
PM peak	76%	91%
Overnight	67%	86%

In addition, travel times along the Golden Mile which are critical for correct estimation of modal share in the Wellington CBD were also compared with observed and were found to be a good match for all time periods and both directions.

6. Rail patronage

6.1 Summary

No new survey was carried out for 2018 rail patronage, and unlike bus demand with ETM data, no recent disaggregated information was available. Four main sources of data were investigated to derive observed rail patronage:

- **Rail automated door counts:** train carriages on the Wellington railway network are equipped with Automatic Passenger Counts (APC) on all doors, which count the number of passengers boarding and alighting at each station. APC data for November 2019 was provided by GWRC and factored to March 2018 using Metlink data of patronage per line.
- **KiwiRail high counts:** these (also called 'guard counts') are manual counts of the maximum load of passengers on each train, i.e. counts of passengers directly before entering Wellington station for inbound services or after leaving the station for outbound services. Data for November 2019 was provided by GWRC.
- **2017 Park-and-Ride survey and APC:** a survey of access to rail and park-and-ride use was commissioned in June 2017 by GWRC¹. Processed data from this survey, including 2017 APC data that was used to expand it, was provided and used to check modelled mode access to rail. The 2017 APC was also used to check consistency with 2019 APC data.
- **2011 rail survey:** this is detailed data collated for the development of the 2011 WPTM, based on an extensive survey of rail patronage.

Upon analysis of the APC counts, it was clear that these counts were not overly accurate both in terms of number of passengers counted and categorisation of boardings vs alightings. Results showed that in the peak direction (AM inbound and PM outbound), automated door counts consistently underestimated the number of passengers in and out of Wellington station. During the Inter-peak, this trend was even more apparent, and in the counter-peak direction estimating high counts using automated door data actually led to negative values (meaning that in the AM peak outbound direction more boardings than alightings were recorded, excluding Wellington station). Following discussions with GWRC, it was understood that some door counters were faulty and incorrectly separated boardings from alightings.

One approach initially tested was to use 2019 total number of passengers at each station from APC but apply the 2011 split between boardings and alightings. However, it was found during validation of the model that using this approach to estimate 2011-2018 observed changes in patronage per station still led

¹ <http://www.gw.govt.nz/assets/2017-Rail-Survey-report20-07-2017.pdf>

to overall trends per line that were counter-intuitive and did not match the increase in patronage per line observed using the more reliable high counts.

Ultimately, for the data used for individual count validation and loading profiles, it was decided to continue to use the 2011 observed boardings and lightings per station, factored up using overall patronage data for each line.

This approach means that patronage increases for some stations having experienced more intense growth since 2011 may not be fully reflected in the data used for validation, and it is recommended that the model is checked against more recent patronage data should it become available.

6.2 Guard counts

First, modelled peak direction rail volumes at Wellington station were compared against rail high (or guard) counts obtained from KiwiRail, separately for each railway line. Results are shown in the following table, with the GEH calculated based on the average hourly volume.

Table 6.1: Rail high counts validation

Line	Observed (3 Hour)	Modelled (3 Hour)	Difference	% Difference	GEH
AM Peak - Inbound					
Johnsonville	1,632	1,347	-285	-17%	4.3
Hutt Valley / Melling / Wairarapa	8,205	8,392	187	2%	1.2
Kapiti	6,349	7,112	763	12%	5.4
Total	16,186	16,851	665	4%	3.0
PM Peak - Outbound					
Johnsonville	1,319	1,351	32	2%	0.5
Hutt Valley / Melling / Wairarapa	6,873	6,736	-137	-2%	1.0
Kapiti	5,409	5,832	423	8%	3.3
Total	13,601	13,919	318	2%	1.6

Results of the comparison show that the model replicates the peak direction patronage well to and from Wellington rail station for each line, with the most notable difference being the Kapiti line in the AM peak with a GEH of 5.

6.3 Individual counts

This section presents a comparison of observed and modelled rail passenger volumes at a number of locations on the rail network. Note that screenline results are not shown as each screenline would effectively be a single count for rail.

For observed demand, APC door counts were not used for the AM Peak and Inter-peak due to the accuracy issues mentioned previously. Observed was therefore based on boardings and alightings from the 2011 platform surveys, factored up using Metlink patronage data.

The PM peak was not surveyed in 2011, however, as it was not originally included in the WPTM. 2018 APC data was therefore used for boardings, while alightings (which were too unreliable to use) were based on AM peak boardings at the same station, factored to match PM boardings on the whole route.

No reliable data was available for the Overnight period, which has generally low levels of rail patronage, and this period was not included in the validation.

Results are shown in the following table, and then plotted as scattergrams.

Table 6.2: Individual count validation – rail patronage

Criteria		AM	IP	PM
GEH	>50% with GEH<5	56%	89%	61%
	>60% with GEH<7.5	83%	100%	78%
	>70% with GEH<10	100%	100%	83%
	>85% with GEH<12	100%	100%	100%
Other	Slope of trendline between 0.85 and 1.15	0.96	1.24	1.01
	r2 > 0.8	99%	97%	99%

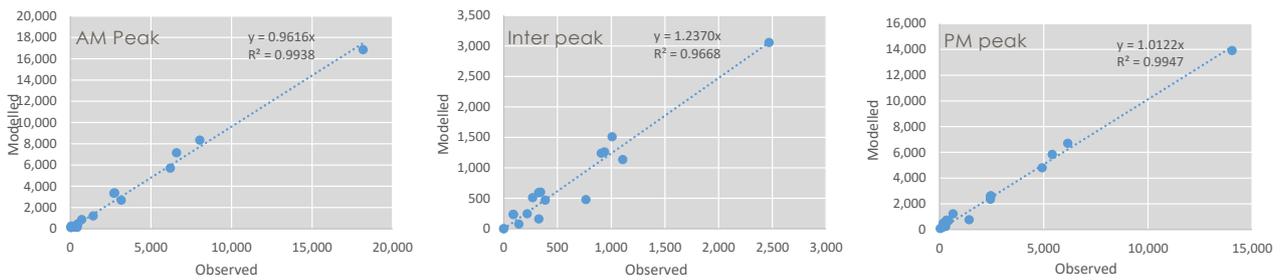

Figure 6.1: Screenline validation scatterplots – Rail patronage (period flows)

Overall results show that the model meets all TMDG guidelines, with the exception of the slope of the trendline for the Inter-peak. This indicates that rail patronage is overestimated in the Inter-peak period. Rail passenger demand is however very low during this period (hourly volumes are less than 10% of the average hour of the peak periods) and this is therefore considered acceptable, as reflected by the good GEH performance. This should however be taken into account if using model output specifically for the Inter-peak.

The detailed results are included in Appendix C, and show the following:

- The main screenline for trips directly arriving to/departing from Wellington station in the CBD (W4) performs well for all time periods and direction, with the exception of the PM inbound with a GEH of 11. This is the counter-peak direction with low volume and is therefore not considered critical.
- In the AM peak, the main discrepancy is for screenlines L2 and U2 (respectively Lower Hutt North and Upper Hutt South) which are located close together and show the same pattern of modelled trips being about 25% higher than observed, with a GEH of 6-7.
- A number of screenlines, especially in the PM peak show the same pattern as W4 with modelled trips being too high in the counter-peak direction, although these all have low volumes.

6.4 Patronage loading profiles

The following plots compare modelled and observed boardings and alightings for each railway line (with Melling and Wairarapa lines combined with the Hutt Valley line) in the peak direction, and show the resulting patronage profiles. Observed is based on the same data as the individual counts, i.e. 2011 surveys factored up using Metlink patronage for the AM peak and Inter-peak, and adjusted 2018 APC counts for the PM peak.

As is generally the case for strategic models, patronage profile validation for the counter-peak direction and Inter-peak is not as good, and was not included in this analysis due to the low levels of patronage both observed and modelled (consistent with previous versions of WTSM). In this case however, the comparison would have been made even more difficult due to the data used for comparison being more unreliable.

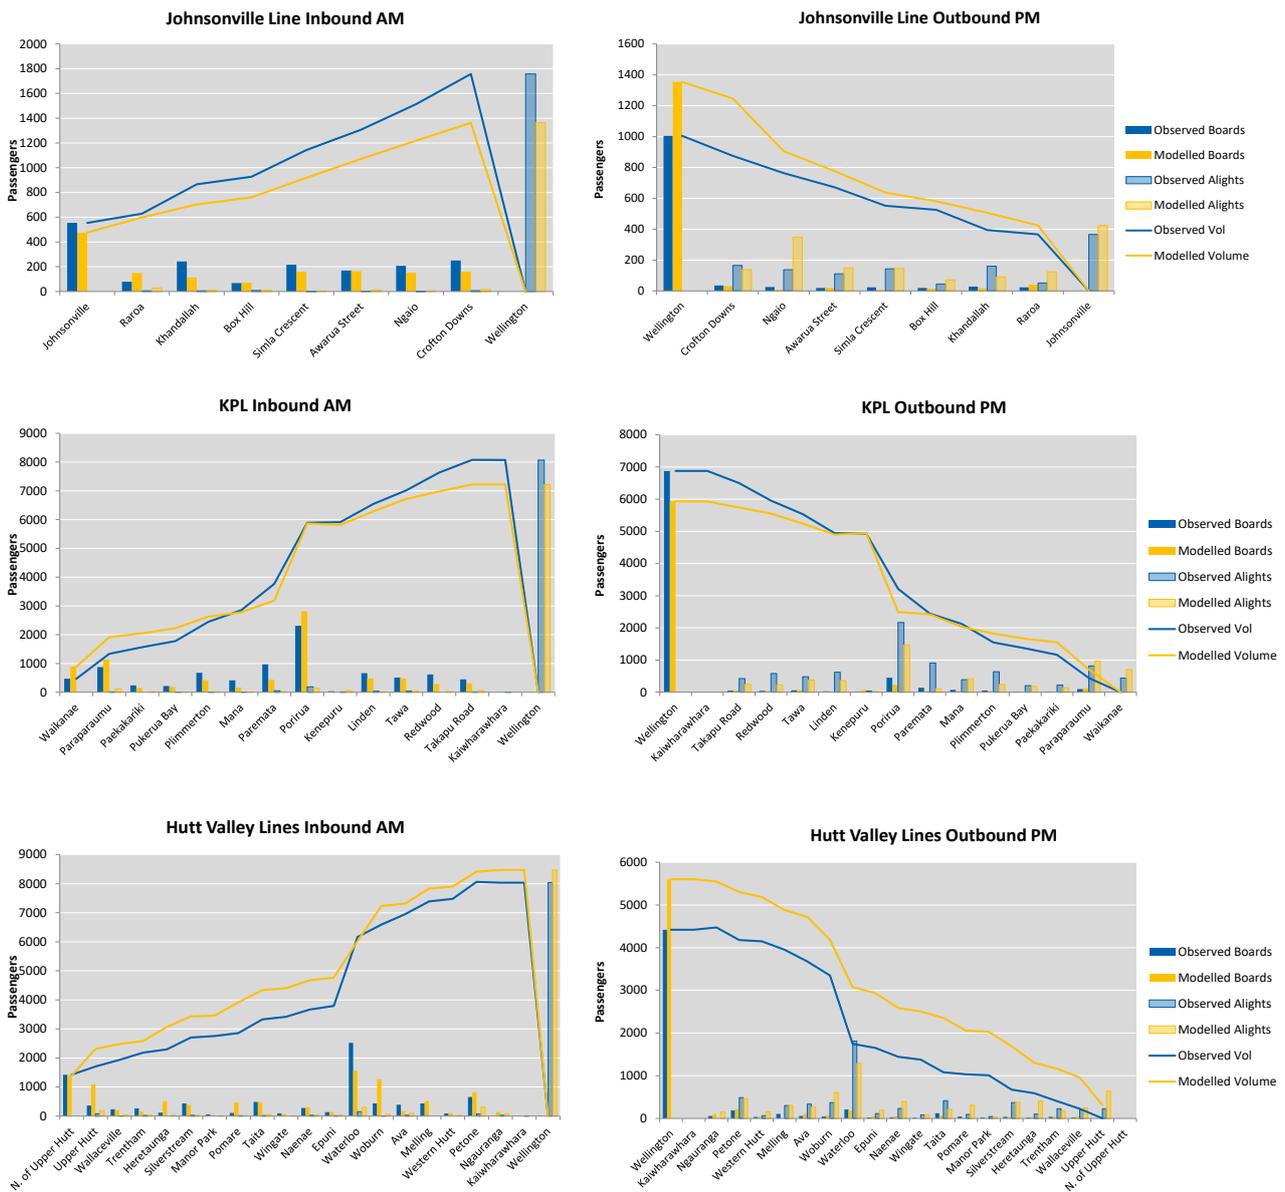

Figure 6.2: Rail loading profiles for peak direction (3-hour)

This comparison shows that the overall “shape” of the modelled loading profile is a good match with observed, with patronage at most stations also being relatively close. However, there are some clear differences, including total boardings at Wellington station in the PM peak for the Johnsonville and Hutt Valley lines which are quite high in the model. This does not tally with guard counts which show the model being much closer to observed, highlighting some of the limitations with the observed data used for comparison as detailed above.

Other differences include the higher modelled boardings at Waikanae and Paraparaumu, for which the 2011 boardings factored up using growth on the whole line likely do not represent the high growth in patronage that is known to have occurred since at these stations.

In order to provide a more reliable comparison, passenger loadings were also produced using the more recent 2019 APC counts and the 2017 park-and-ride survey, but this time looking only at boardings along the route and not taking into account alightings (which were too unreliable in the former and not included in the latter).

Due to the large majority of rail passengers travelling to Wellington station, this was deemed to be a useful comparison despite not considering alightings, and which would account for more recent localised changes in patronage. This analysis was however only possible for AM peak inbound passengers.

Results are shown in the following figures which show the loading profiles based on boardings only for all three main rail lines and for peak period volumes.

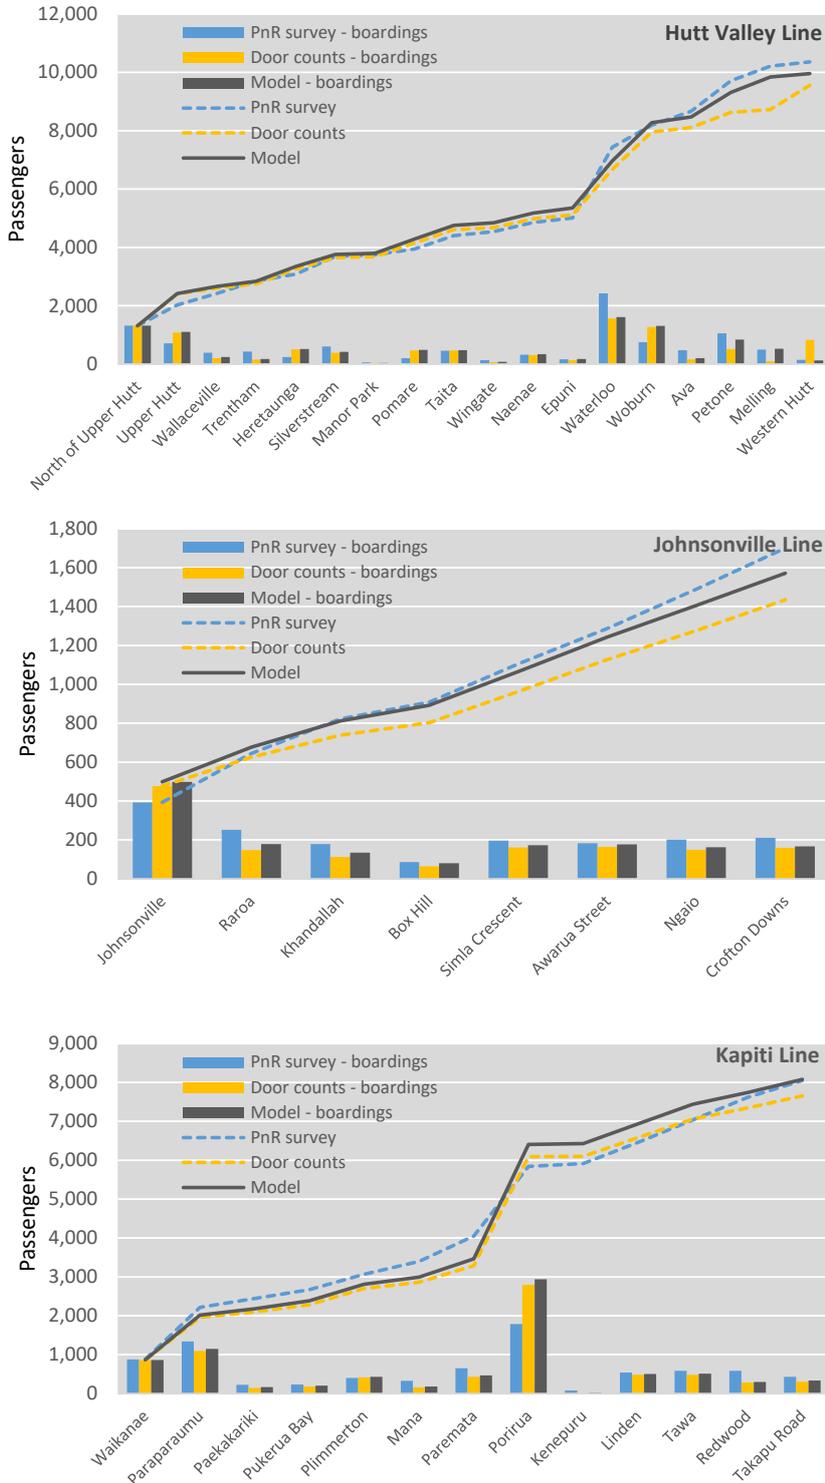

Figure 6.3: Rail loading profiles AM Peak – boardings only (3-hour)

The model clearly performs better compared against these loading profiles based on more recent and accurate datasets, although the limitation that these are based on boardings must be borne in mind.

6.5 Access to rail

This section presents a comparison of observed versus modelled access to rail by mode, including park-and-ride, kiss-and-ride, and other (mostly walk) for the AM peak.

Observed data was sourced from the 2017 rail survey, which used APC data to expand the sample. This comparison is however provided as a high level check that shares of rail demand by access mode resulting from the mode choice component of WTSM are a good match with the most up-to-date observed data.

The table below shows a comparison of access mode shares for each rail line and overall.

Table 6.3: Access to rail validation

Line	Observed			Modelled		
	Park-and-ride	Kiss-and-ride	Other	Park-and-ride	Kiss-and-ride	Other
Johnsonville	23%	1%	76%	25%	8%	67%
Hutt Valley / Melling / Wairarapa	44%	7%	49%	43%	11%	46%
Kapiti	52%	9%	39%	49%	7%	44%
Total	46%	7%	47%	44%	9%	47%

This comparison shows that the model correctly reproduces modal access to rail overall, with the result per line also being reasonably close. The main difference is for the Johnsonville line with an overestimation of kiss-and-ride access but the difference is deemed acceptable, being circa 100 passengers.

7. Active modes

Active modes including walk and cycle are represented as a single demand segment in WTSM (although an additional module was subsequently added that splits this demand into separate walk and cycle matrices, which is separately described in 'TN23 – Active modes'). This demand is produced as 24hr production-attraction matrices, and is not then factored to origin-destination by time period as are other modes.

In addition, little observed data is available to compare against for active modes, with the only source being the Wellington CBD cordon survey, carried out between 7 and 9am in a single weekday in March.

This data was however used as a coarse check that the model is a suitable match based on the start point of active trips to the CBD. As active modes are not assigned in WTSM, sectorised matrices were used instead to aggregate trips to the CBD by production sector.

The different nature of both datasets must be kept in mind for this comparison (2hr AM peak vs daily, origin-destination vs production-attraction), as a result the actual number of trips were very different and only the spatial distribution as a percentage per sector was used.

Results are presented in the following table, with the model reflecting well the broad distribution of observed trips, albeit at a very coarse level.

Table 7.1: Active mode trips to CBD by area

Origin sector	CBD cordon	Model
South-east suburbs	41%	42%
Western suburbs	33%	35%
Northern suburbs and rest of region	27%	23%

8. Model convergence

Finally, convergence of the demand-assignment loops is also reported to ensure that the WTSM is internally consistent, i.e. the demand that is assigned on the network produces delays and generalised costs which are in turn consistent with the demand itself at convergence. This also ensures that the model is stable enough for scenario appraisal.

The WTSM, as a 4-step model, iterates over a number of loops with trip distribution, modal choice and assignment being run in sequence for each iteration until the model converges to a stable outcome. The model convergence is checked after each iteration by undertaking a comparison of current demand with demand from the previous iteration. Two criteria are used:

- the root mean square error (RMSE) of matrices between the current and the previous iteration being less than 0.01.
- Less than 5% of demand matrix non-zero cells showing a change greater than 5% between the current and previous iteration.

The second check was used as RMSE is not always suitable for matrices with low demand and many cells with zero values. This is the case for most PT matrices, which tend to return low RMSE values after a few iterations. Matrices for car and public transport modes and for all time periods need to match these criteria for convergence to be achieved.

For the validated base year 2018 scenario, the model was found to converge after five iterations, with an “initialisation” assignment (i.e. iteration 0) based on observed matrices to generate the first set of generalised costs. The two following plots show the convergence results for both criteria. Note that for clarity not all time periods are shown, with each point on the plot showing the worst-performing time period for each mode and iteration instead.

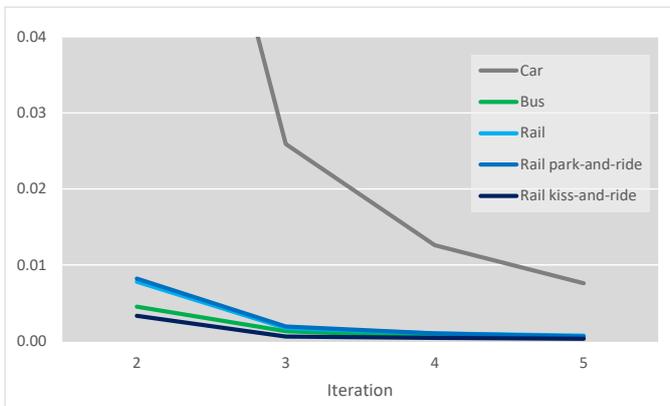

Figure 8.1: Demand convergence – RMSE

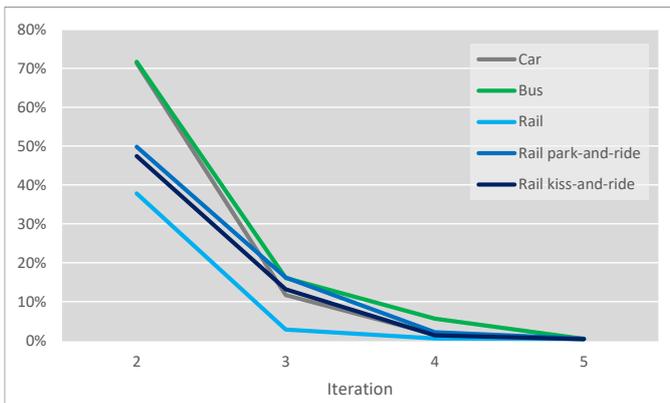

Figure 8.2: Demand convergence – ODs with >5% difference

Looking at forecasting years the model converges after 8 iterations for a standard 2053 forecasting including significant population growth assumption. With the crowded PT assignment functionality turned on, that applies capacity constraints on the PT network, this increased to 10 iterations.

In addition to these demand checks, assignment convergence was also checked to ensure that total vehicle-kilometres and vehicle-hours travelled across the whole network changed by less than 0.1% between the current iteration and the previous one.

Results are presented in the following table which shows the total vehicle-kilometres travelled and vehicle-hours travelled (in 1000s), as well as the percentage change between iterations. Results are for the modelled period in all cases (i.e. not an average hour).

Table 8.1: Assigned VKT and VHT convergence

Iteration	AM Peak		Inter-peak		PM Peak		Overnight	
	veh.km	veh.hr	veh.km	veh.hr	veh.km	veh.hr	veh.km	veh.hr
1	1,685	2678.1	2,924	3944.8	2,038	3339.0	1,803	2197.1
2	1,654	2544.4	2,838	3849.3	2,000	3115.2	1,774	2166.5
	-1.83%	-4.99%	-2.93%	-2.42%	-1.88%	-6.70%	-1.63%	-1.39%
3	1,658	2556.0	2,878	3852.9	2,003	3125.8	1,777	2168.7

	0.04%	0.03%	0.02%	-0.03%	0.02%	0.07%	0.02%	0.02%

9. Validation summary

This report has detailed the performance of the new Wellington Transport Strategy Model in reproducing observed multi-modal travel patterns and counts in the Wellington region against a range of metrics. Validation criteria were mostly based on the Transport Model Development Guidelines and criteria for a model type 'A – Regional' were used, consistent with the strategic nature of the WTSM.

For the large majority of criteria, the new WTSM achieves the targets set out in the TMDG, and significantly outperforms the previous version. Results can be summarised as follows:

- **Light vehicles validation:** both screenline and individual count validation show the model performing well, with some caveats that are consistent with limitations seen in strategic models (percentage difference for screenlines, GEH<5 for individual counts, representation of CBD traffic) but that must be considered if looking at detailed model outputs.
- **Heavy vehicles validation:** meets the GEH targets for screenlines and individual links and the absolute difference for links, however, these criteria are not designed for heavy vehicles which are numerically small. At a screenline level, the R-squared values are considered acceptable for all periods albeit with more variation than for light vehicles. At the individual link level, there is more variation between modelled and observed compared with screenlines, which is not unexpected.
- **Private vehicle travel times:** the model performs well in reproducing observed travel times. The main difference can be seen on the SH2 between Lower Hutt and Ngauranga where the model tends to return slow speeds in the peak direction.
- **Bus patronage:** modelled volumes compare well with the assigned reference matrix built from ETM data used to produce "observed" volumes, achieving all TMDG criteria. The main issue appears to be an underestimation of inbound patronage from North Wellington to the CBD in the AM peak, however this is not apparent if looking at comparisons against the CBD cordon survey for which the model validates well. This should be investigated in more detail if further data is available.
- **Bus travel times:** the model is a good representation of bus travel times, including along the Golden Mile in the CBD.
- **Rail patronage:** while availability of recent and accurate disaggregate observed data was an issue for validation, the model overall performs sensibly against a range of data, including the more aggregate but accurate high counts.
- **Active modes:** comparison against observed data was very limited for these modes, but a high level check of sectorised distribution of trips to the CBD indicates that the WTSM broadly replicates observed patterns.

Results from this analysis show that the new version of WTSM achieves adequate validation expected from a strategic model.

The model also achieves convergence in base and future years, demonstrating stability of output.

In addition, sensitivity tests were carried out separately to show the model response to changes in input costs and parameters. These are reported in 'TN29 – Trip distribution and mode choice', and it was found that the demand model responses were within expected ranges and elasticity guidelines.

However, and as with all such strategic models, care must be taken when looking at more disaggregate model output, with local validation checks potentially carried out.
